A large arterial aneurysm is uncommon in the upper extremity. The ulnar artery is the most common site. An aneurysm of this size may be present without significant clinical symptoms; however, distal arterial ischemia is the main concern and one of the most difficult to treat. Although limb salvage has been reported, the timing of surgery, the technique of revascularization, and the choice of autograft is not well defined. We describe a patient with an aneurysm of the ulnar artery, who underwent aneurysmectomy, end-to-end anastomosis, and carpal tunnel decompression. Postoperative arteriography showed no complications or thrombosis of the bypass. We conclude that in limb salvage when the primary goal is to maintain the most viable tissue, carpal tunnel decompression should be considered.// RUN:
